**AXA Research Fund**

17/08/2017

**Goldschmidt, Paris**

Models typically assume **globally uniform** physical and chemical dust **properties** despite known regional variations in the mineral content of the parent soil and the emitted dust aerosols

Courtesy Robert Green (JPL)

**Shortwave absorption**  
hematite

**Longwave absorption**  
calcite, clays, quartz

**Nucleation of ice crystals**  
feldspars and clays

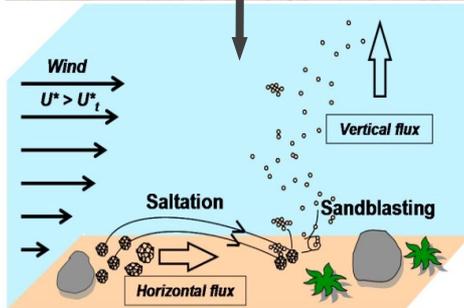

**Heterogeneous uptake**  
e.g. calcite

**Partitioning of semi-volatile inorganic compounds**  
K, Ca, Mg, Na

**Bioavailable iron**  
clays and iron oxides

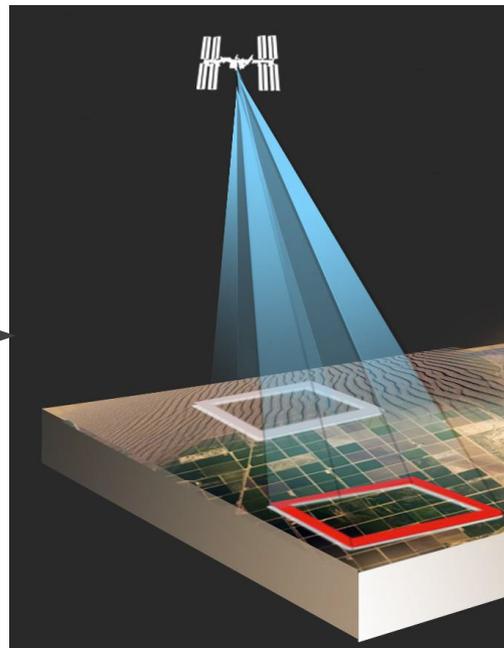

## Constraining the size-resolved mineral composition

Field campaigns  
Theory

**Emitted dust PSD**  
**Size-resolved minerals**

Imaging spectroscopy  
field-airborne-spaceborne

**Improvement of soil  
mineralogical atlases**

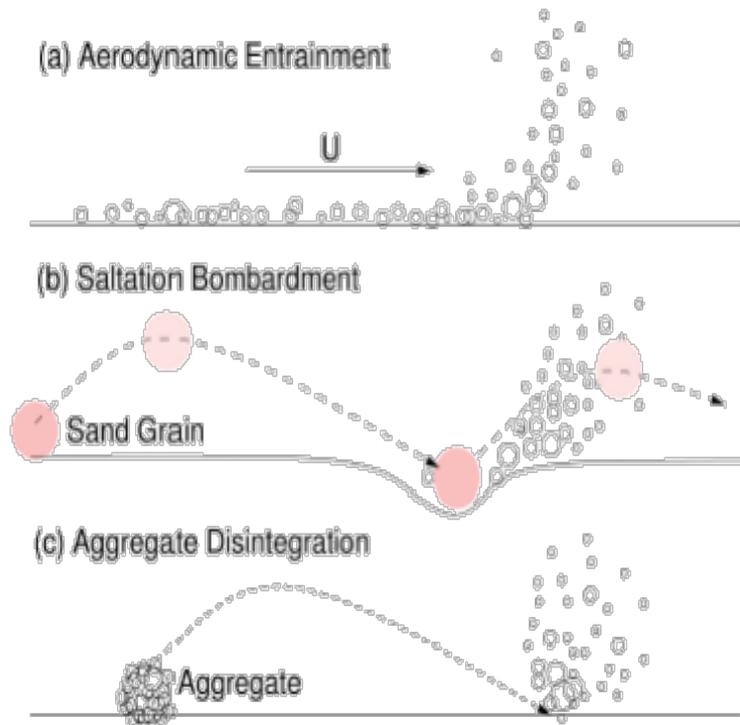

State-of-the art

Problems

Questions

How to tackle them?

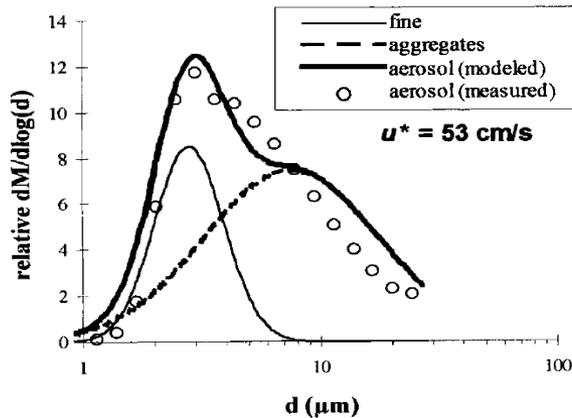

## Emitted PSD of dust minerals is critical to properly quantifying their climate effect

### Even disregarding the complexity of mineralogy

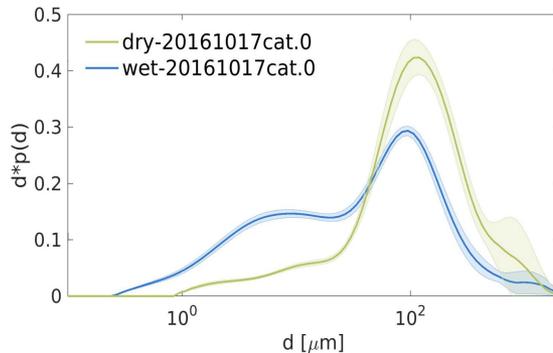

- Incomplete understanding of the physics
- Paucity and incompleteness of measurements
- Contradiction among theories, field observations and wind tunnel experiments

From Shao et al. 2011

## Alfaro et al. – Dust Production Model

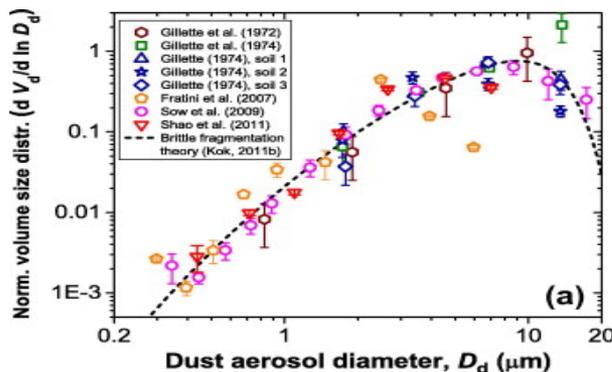

- Three lognormal modes
- Bonding energy of aggregates
- Kinetic energy of saltators
- PSD depend on wind (based on wind tunnel)

## Shao model

- Weighted average between disturbed and undisturbed PSD
- Weighting factor  $\sim 2$  empirical coeffs and wind
- PSD depends on wind (based on wind tunnel)
- Revised version in 2011 based on measurements

Courtesy Martina Klose

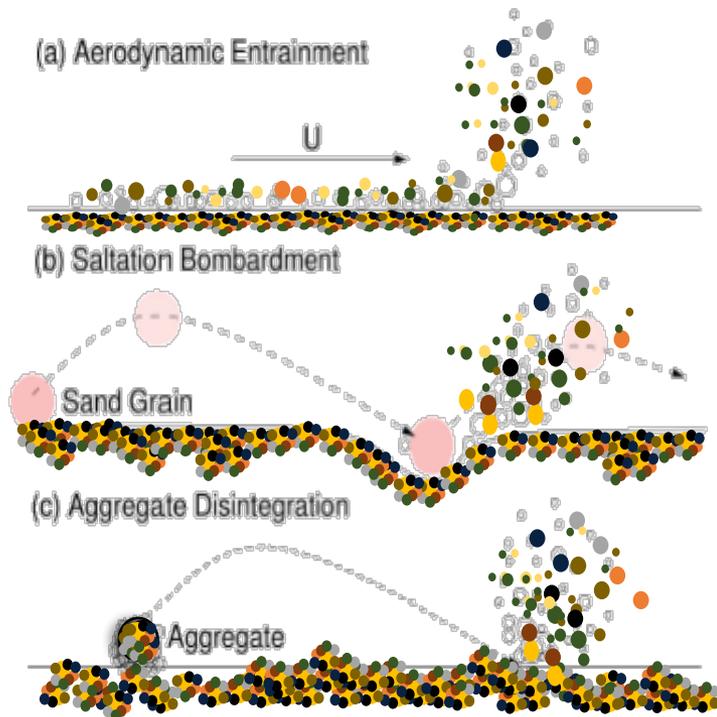

## Kok model (brittle fragmentation)

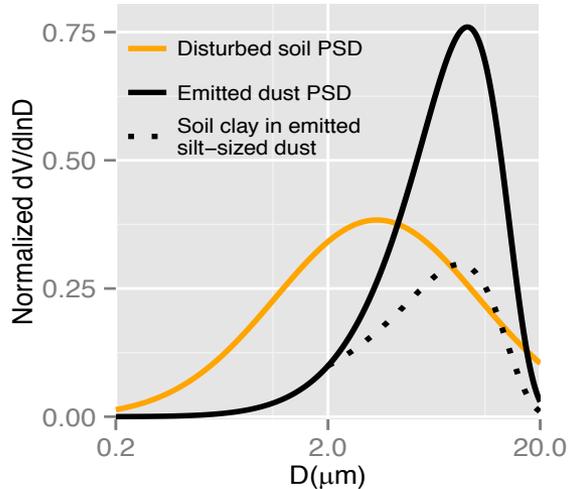

- Following the physics of brittle materials
- Emitted PSD independent of both the undisturbed soil PSD and the wind speed
- Dispersed soil PSD and the side crack propagation length ( $\lambda$ ) assumed constant

- Does dust PSD depend on wind speed?
- Lognormal modes, binding forces, empirical coefficients are soil-specific?
- Range of variability of  $\lambda$  in BFT?
- $\lambda$  dependencies such as dry aggregate stability?
- How can we account for it?
- Emitted PSD and emission mechanism?

## With mineralogy the picture becomes even more complex

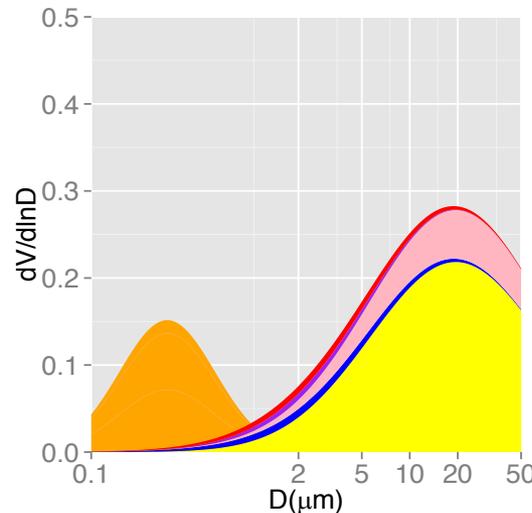

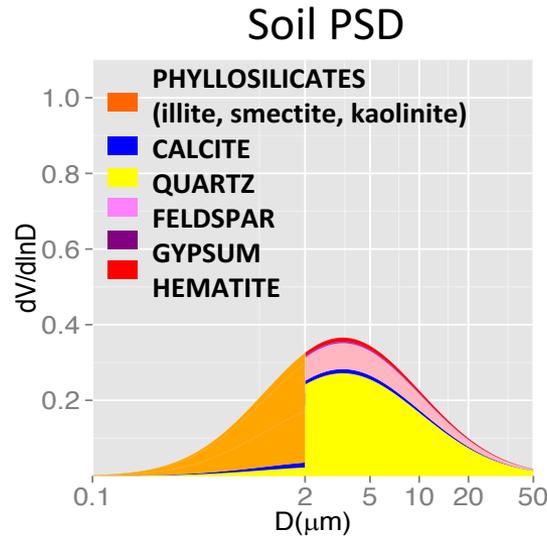

- Complete lack of experimental studies tackling the relationship of the emitted PSD and soil mineralogy
- Mineralogy atlases are extrapolated from a limited amount of measurements based on soil type
- Measurements based upon wet sieving that disturbs the soil samples
- Internal and external mixtures of different minerals
- Iron oxides occur as both small accretions and pure crystalline forms

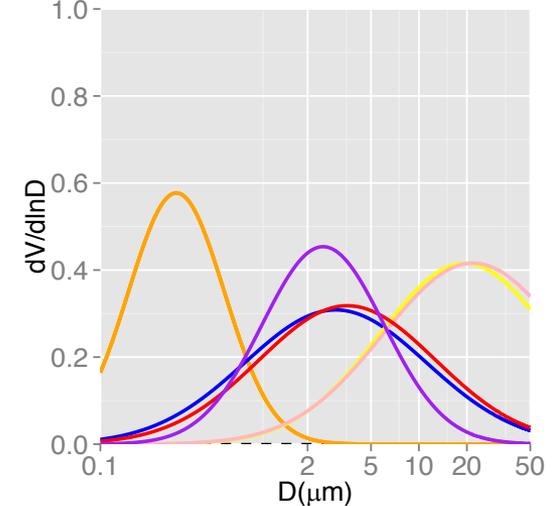

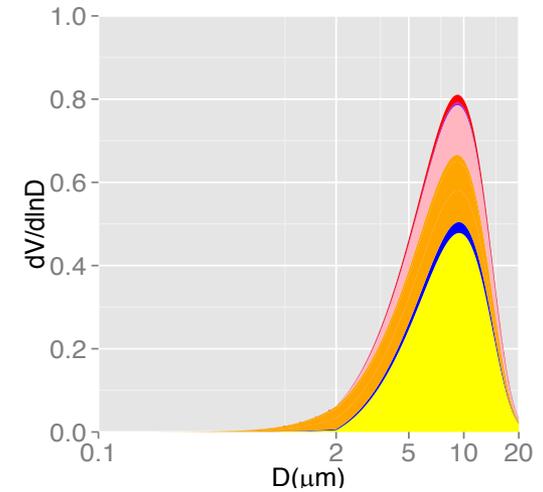

$$\frac{dV}{d\ln D} = \frac{D}{C_V} u(D) \exp \left[ - \left( \frac{D}{\lambda} \right)^3 \right] \quad \text{Kok 2011}$$

BFT auspicious for mineralogy as it is based on the soil dispersed PSD

BFT extensions based on fitting Mineral- specific soil PSD's further improve the results

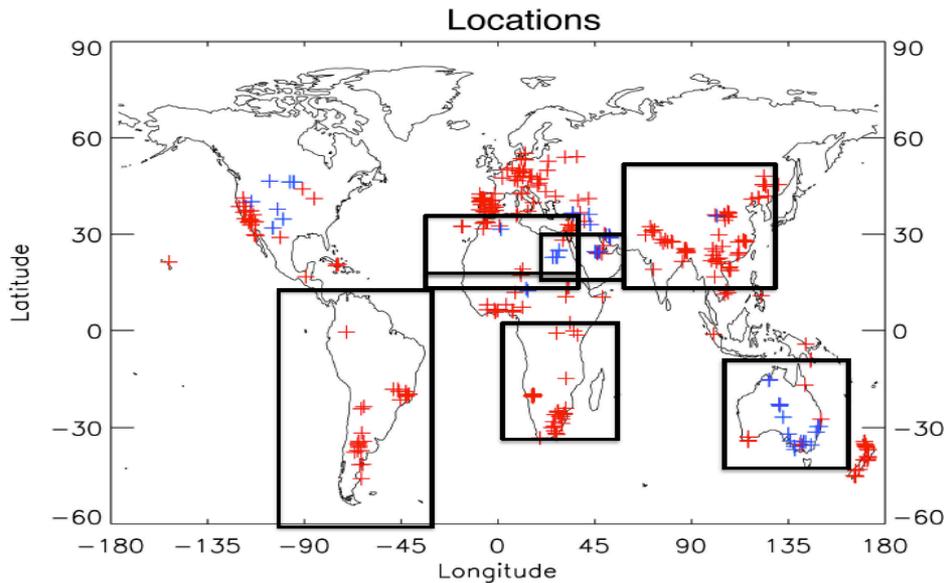

Emitted PSD

Perlwitz et al., 2015a,b  
 Pérez García-Pando et al., 2016  
 Pérez García-Pando et al., in prep

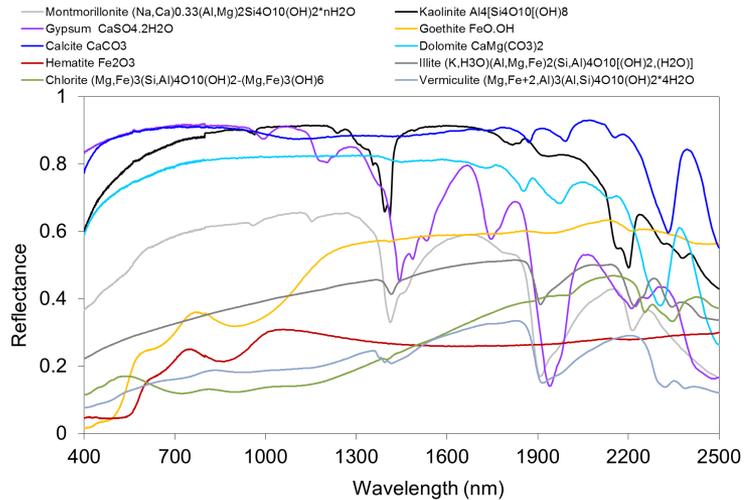

- Observed size-resolved mineralogy of the soil and the emitted dust support BFT and extensions?
- Typical dispersed PSDs for each mineral?
- Emitted mixing state compared to the dispersed and undispersed soil?
- Best strategy to derive the mineral-specific disturbed PSDs from existing global soil texture and soil mineralogy?

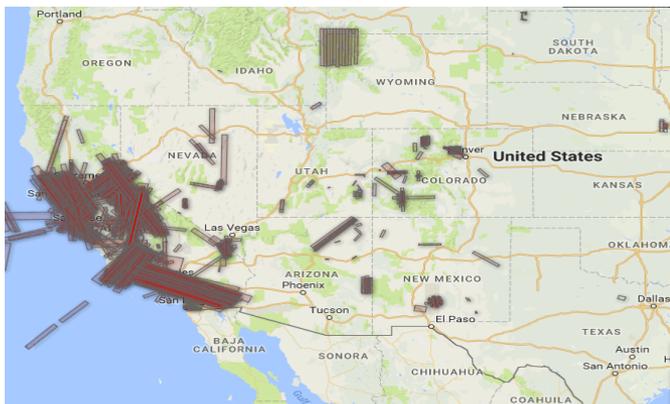

Claquin et al., 1999  
Journet et al., 2014

- Currently 12 key minerals estimated
- 700 soil descriptions sampling 55 % of FAO soil units
- Many regions including prolific sources not sampled
- Massive extrapolation based on soil unit/type
- A number of assumptions to overcome the lack of data: for example on hematite and goethite size

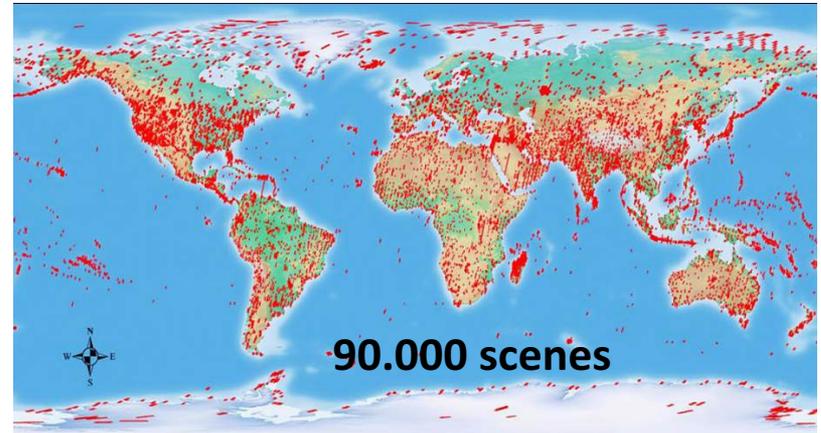

## VSWIR Spectra of Dust Source Minerals

AVIRIS airborne scenes  
 0.4–2.5 μm, 224 bands, 10 nm spectral resolution, SNR of ~500:1

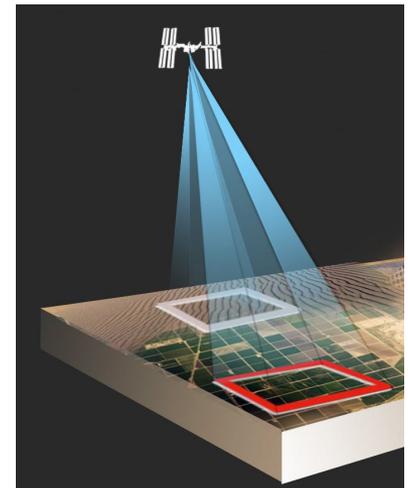

Hyperion: satellite hyperspectral sensor 0.4 to 2.5 μm, 242 spectral bands, 10nm spectral resolution, 30 m spatial with a SNR of ~50:1

Coming soon, e.g.,  
**EnMap (~2019)**  
**Germany**

EMIT (under review)  
**NASA, US**

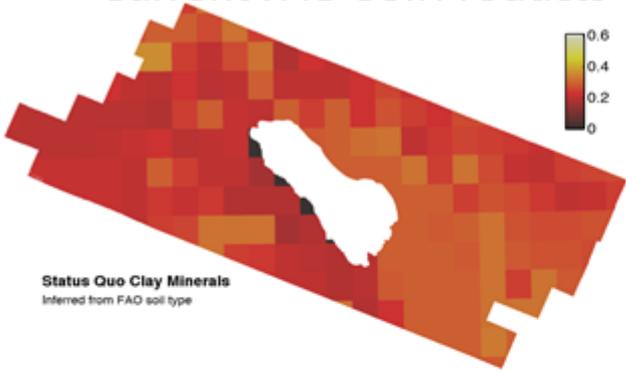

# Coming space borne imaging spectroscopy may help

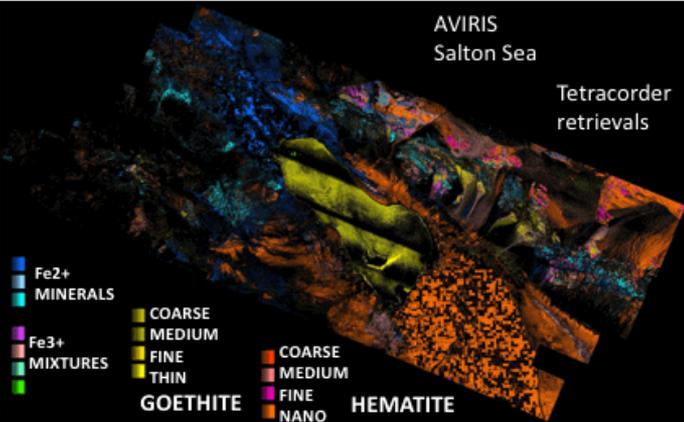

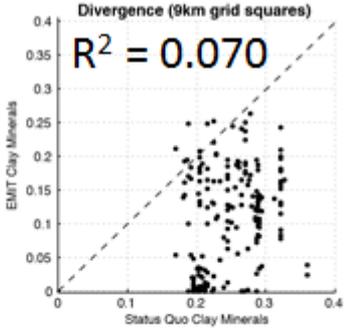

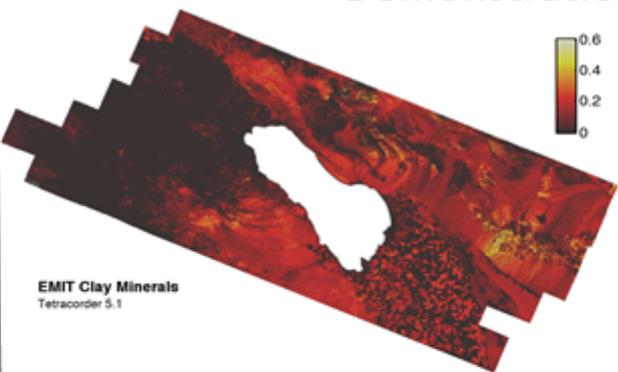

Current VSWIR hyperspectral imaging spectroscopy enables a factor of 1,000,000 improvement knowledge with respect to the current data used to constrain Earth system models for understanding and prediction.

## Salton sea

Current FAO-Soil Products

Demonstration Products

**Caveat:** feldspar and quartz beyond spectral Window covered by planned spaceborne missions

## **Imaging spectroscopy for mineralogical mapping in dust modeling**

- How well is the surface mineralogical composition retrieved compared to field spectroscopy and laboratory measurements of soil samples?
- How does composition vary as a function of grain size retrieved from spectroscopy?
- How do we relate mineral abundance and grain size information derived from spectroscopy to mineral abundance and PSD derived from both disturbed and undisturbed soil samples?
- How homogeneous is the composition of the soil as a function of spatial scale?
- How do we combine existing soil mineralogy atlases with information from spaceborne retrievals?
- Do theoretical and modeling frameworks need to adapt to surface spectroscopic retrievals?

## Field campaigns

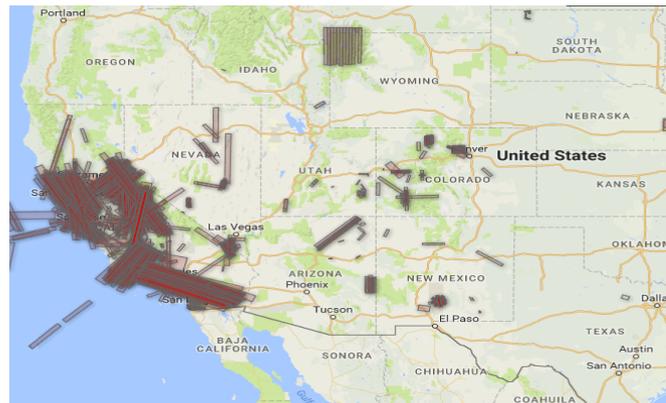

- Variety of soil types, textures and landforms
- Multiannual measurements whenever possible
- Size-resolved dust flux with optical spectrometers, multistage cascade impactors and additional passive samplers
- Saltation sediment with passive samplers and saltation sensors
- Wind and temp profiles, RH close to the ground with meteorological tower
- Soil sampling: stratified random sampling (1cm)
- Soil moisture (max 1cm) with time-domain reflectometry sensors

## Laboratory analysis, theory and hypothesis testing

- **Identifying emission mechanism:** comparing the PSD of the minimally dispersed and dispersed soil and saltation sediment
- **Confronting three main PSD theories, exploring dependencies on wind speed.**
- **Explore potential dependency of  $\lambda$  upon aggregate stability:** mean weight diameter of the minimally dispersed soil PSD and aggregate disintegration after various levels of sonic sieving
- **Size-resolved composition, chemistry, morphology and mixing state of soil and emitted PSD:** X-ray diffraction (XRD); scanning electron microscopy (SEM), X-ray spectroscopy (EDS), backscatter electron diffraction (BSED) -> **testing BFT and extensions**

## Coincident field experiments and available airborne hyperspectral spectroscopy

- Airborne and field spectroscopic measurements
- Spectroscopic measurements of soil samples
- Link/compare to XRD, TEM, SEM and BSED analyses of soil samples and emitted samples
- Comprehensive understanding of the relationship between spectroscopic retrievals and soil analysis in terms of mineral abundances, grain sizes and mixing state
- Relationship to disturbed and undisturbed soil
- Feldspar and quartz undetected -> how to combine mineral abundances and grain sizes from spectroscopy with feldspar and quartz from soil analyses?
